

# Decision Theory

## Lecture 8

# Time to make a decision...

Exercise inspired by Mausam, University of Washington, CSE573

## State of Nature

Poor market performance	Good market performance
<b>Payoff</b>	<b>Payoff</b>

Buy Apple	-1,000	1,700
Buy Google	-2,000	2,100
Buy bonds	10	10

# How to invest?

# Maximax

## Optimism

Select the maximum of the maximum payoff

Action

	State of Nature		Criterion
	Poor market performance	Good market performance	Maximum payoff for an action
	Payoff	Payoff	
Buy Apple	-1,000	1,700	1,700
Buy Google	-2,000	2,100	2,100
Buy bonds	10	10	10

← **Maximax**

# Maximin

## Pessimism

Select the maximum of the minimum payoffs

Action

### State of Nature

### Criterion

Poor market  
performance

Good market  
performance

Minimum  
payoff for  
an action

### Payoff

### Payoff

Buy Apple

← **Maximin**

# Minimax

Select the minimum maximum regret

Action

State of Nature				Criterion
Poor market performance		Good market performance		Maximum regret for an action
Payoff	Regret	Payoff	Regret	
-1,000	1,010	1,700	400	1,010
-2,000	2,010	2,100	0	2,010
10	0	10	2,090	2,090

←  
**Minimax**

Which decision would I regret least?

**Regret = Opportunity loss**

**Next: factor in probabilities of different outcomes**

# Expected Payoff: Equal likelihood

State of Nature

Criterion

Select the highest average payoff ASSUMING all states are of equal probability

Poor market performance

Good market performance

Expected reward/  
payoff

0.5

# Expected Payoff

Action	State of Nature		Criterion	Select the highest average payoff assuming state probabilities from prior knowledge
	Poor market performance	Good market performance	Expected reward/ payoff	
	Payoff	Payoff		
Buy Apple	-1,000	1,700	-190	← <b>Maximum Expected Reward</b>
Buy Google	-2,000	2,100	-770	
Buy bonds	10	10	10	
State Probability:	0.7	0.3		

# Decision making design pattern

1. Define a measure of risk or reward
2. Select the action that optimizes that metric

# Notation

$EV(a_i) = V(a_i|s_0)P(s_0) + V(a_i|s_1)P(s_1)$   
↑  
Expected reward / payoff

## State of Nature (s)

		Poor market performance $s = s_0$	Excellent market performance $s = s_1$	Expected Reward $EV(a_i)$
Action	Buy Apple $a = a_0$	$V(a_0 s_0)$ -1,000	$V(a_0 s_1)$ 1,700	$(0.7)(-1000) + (0.3)(1700)$ <b>= -190</b>
	Buy Google $a = a_1$	$V(a_1 s_0)$ -2,000	$V(a_1 s_1)$ 2,100	$(0.7)(-2000) + (0.3)(2100)$ <b>= -770</b>
	Buy bonds $a = a_2$	$V(a_2 s_0)$ 10	$V(a_2 s_1)$ 10	$(0.7)(10) + (0.3)(10)$ <b>= 10</b>

State Probability:  $P(s_0) = 0.7$                        $P(s_1) = 0.3$

# Risk = expected loss (cost)

**Loss:**  $\lambda(a_i | s_j) \triangleq$  Loss incurred by choosing action  $i$  and the state of nature being state  $j$

**Risk:**  
Expected loss  $R(a_i) = \sum_{j=1}^{N_s} \lambda(a_i | s_j) P(s_j)$

**Goal:** Select action  $i$  for which  $R(a_i)$  is minimum

# Payoff

# Investments: loss

$$R(a_i) = \lambda(a_i|s_0)P(s_0) + \lambda(a_i|s_1)P(s_1)$$

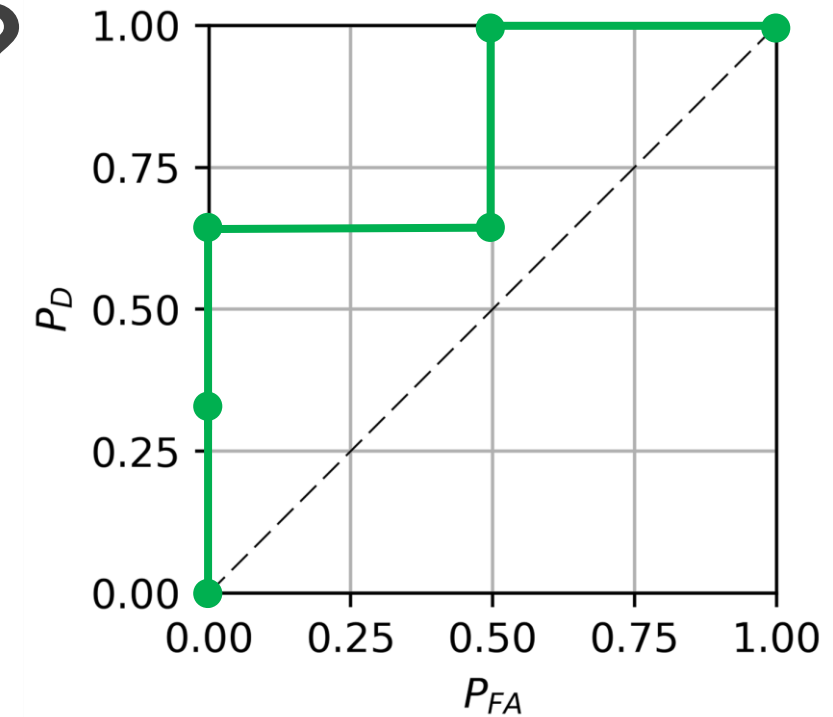

↑  
Risk (Expected loss)

		State of Nature (s)		Risk (Expected Loss) $R(a_i)$
		Poor market performance $s = s_0$	Excellent market performance $s = s_1$	
Action	Buy Apple $a = a_0$	$\lambda(a_0 s_0)$ 1,010	$\lambda(a_0 s_1)$ 400	$(0.7)(1010) + (0.3)(400)$ = <b>827</b>
	Buy Google $a = a_1$	$\lambda(a_1 s_0)$ 2,010	$\lambda(a_1 s_1)$ 0	$(0.7)(2010) + (0.3)(0)$ = <b>1407</b>
	Buy bonds $a = a_2$	$\lambda(a_2 s_0)$ 0	$\lambda(a_2 s_1)$ 2,090	$(0.7)(0) + (0.3)(2090)$ = <b>627</b>
State Probability:		$P(s_0) = 0.7$	$P(s_1) = 0.3$	

**How does this relate to supervised learning?**

# Where to operate along ROC?

		State of Nature	
		Class 0	Class 1
Estimate	Class 0	$\lambda_{00} = \mathbf{0}$	$\lambda_{01} = \mathbf{100}$ False negative
	Class 1	$\lambda_{10} = \mathbf{1}$ False positive	$\lambda_{11} = \mathbf{0}$

$$\lambda_{ij} = \lambda(a_i | s_j)$$

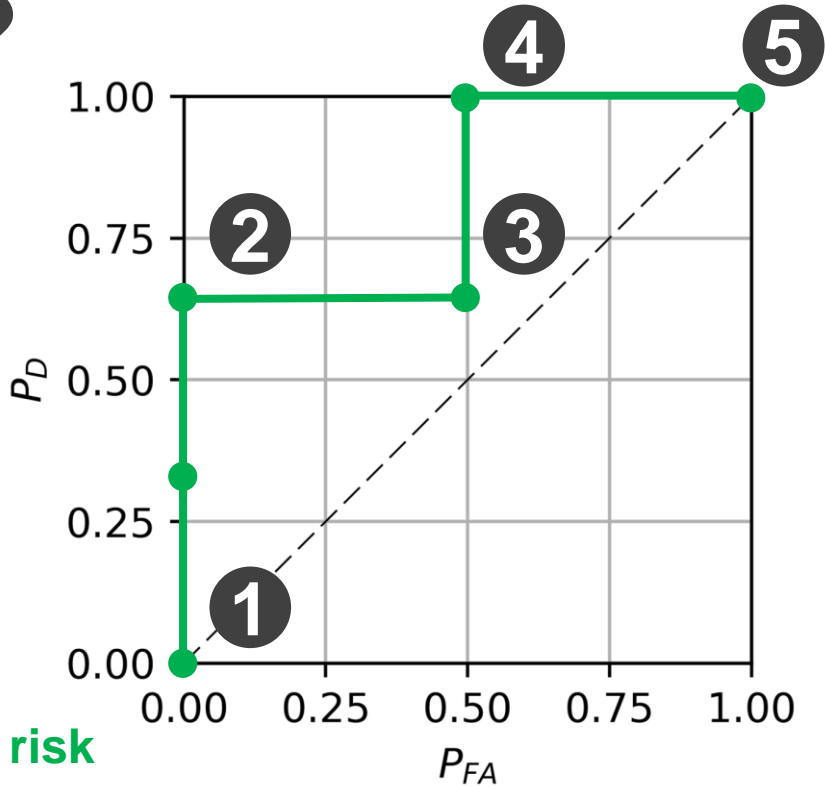

Loss from classifying  
as class  $i$  when state of  
nature is class  $j$

- Assume our classification problem is landmine detection
- A false alarm wastes some time and resources, but a missed detection may cost a life

# Where to operate along ROC?

Action: select operating point $i$	Probability of false alarm $P_{FA}$	Probability of missed detection $(1 - P_d)$	Risk $R(a_i)$
1	0	1	100
2	0	0.33	33
3	0.5	0.33	33.5
4	0.5	0	0.5
5	1	0	1

$$R(a_i) = \sum_{j=1}^{N_s} \lambda(a_i|s_j)P(s_j)$$

$$R(a_i) = \lambda_{10} \underline{P_{FA}(i)} + \lambda_{01} (1 - \underline{P_D(i)})$$

Prob of false alarm
 Prob of missed detection

Estimate

Class 0
 Class 1

	Class 0	Class 1
Class 0	$\lambda_{00} = 0$	$\lambda_{01} = 100$
Class 1	$\lambda_{10} = 1$	$\lambda_{11} = 0$

# Let's generalize this to any binary classifier

This is how to pick what decision threshold to use for a binary classifier

# Defining risk for binary decisions

		State of Nature	
		Class 0 $s = s_0$	Class 1 $s = s_1$
Estimate	Class 0 $a = a_0$	$\lambda(a_0 s_0)$ $\lambda_{00}$	$\lambda(a_0 s_1)$ $\lambda_{01}$
	Class 1 $a = a_1$	$\lambda(a_1 s_0)$ $\lambda_{10}$	$\lambda(a_1 s_1)$ $\lambda_{11}$

$\lambda_{ij}$  = Loss when you classify as class  $i$  when state of nature is class  $j$

$$R(a_0|\mathbf{x}) = \lambda_{00}P(s_0|\mathbf{x}) + \lambda_{01}P(s_1|\mathbf{x})$$

$$R(a_1|\mathbf{x}) = \lambda_{10}P(s_0|\mathbf{x}) + \lambda_{11}P(s_1|\mathbf{x})$$

Probability from classifier  
(i.e. confidence score)

$$P(s_i|\mathbf{x}) = \frac{P(\mathbf{x}|s_i)P(s_i)}{P(\mathbf{x})}$$

**1**

Define the risk associated with each of the two actions

$$R(a_0|\mathbf{x}) = \lambda_{00}P(s_0|\mathbf{x}) + \lambda_{01}P(s_1|\mathbf{x})$$

$$R(a_1|\mathbf{x}) = \lambda_{10}P(s_0|\mathbf{x}) + \lambda_{11}P(s_1|\mathbf{x})$$

**2**

Create a decision rule based on the data

If  $R(a_0|\mathbf{x}) < R(a_1|\mathbf{x})$  then  $a_0$  (decide class 0)

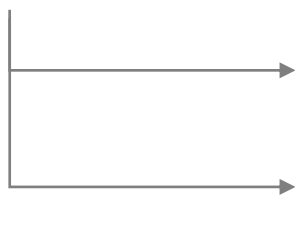

Else  $R(a_0|\mathbf{x}) > R(a_1|\mathbf{x})$  then  $a_1$  (decide class 1)

We choose the rule to **minimize the risk**

**3**

Express this rule in terms of the output from the classifier

$$\lambda_{00}P(s_0|\mathbf{x}) + \lambda_{01}P(s_1|\mathbf{x}) > \lambda_{10}P(s_0|\mathbf{x}) + \lambda_{11}P(s_1|\mathbf{x})$$

$$\frac{P(s_1|\mathbf{x})}{P(s_0|\mathbf{x})} > \frac{\lambda_{10} - \lambda_{00}}{\lambda_{01} - \lambda_{11}} \quad \text{then } a_1$$

This can be applied to any model that outputs posterior probabilities (**discriminative or generative models**)

4

Use Bayes rule to express this as a function of likelihoods

$$\frac{P(s_1|\mathbf{x})}{P(s_0|\mathbf{x})} > \frac{\lambda_{10} - \lambda_{00}}{\lambda_{01} - \lambda_{11}}$$

$$P(s_i|\mathbf{x}) = \frac{P(\mathbf{x}|s_i)P(s_i)}{P(\mathbf{x})}$$

$$\frac{P(\mathbf{x}|s_1)P(s_1)}{P(\mathbf{x}|s_0)P(s_0)} > \frac{\lambda_{10} - \lambda_{00}}{\lambda_{01} - \lambda_{11}}$$

then  $a_1$  (decide class 1)

5

The decision rule can be expressed as a **likelihood ratio**

$$\frac{P(\mathbf{x}|s_1)}{P(\mathbf{x}|s_0)} > \left( \frac{\lambda_{10} - \lambda_{00}}{\lambda_{01} - \lambda_{11}} \right) \frac{P(s_0)}{P(s_1)}$$

Can easily factor in prior knowledge about the classes

then  $a_1$  (decide class 1)

else  $a_0$  (decide class 0)

This can be readily applied to **generative models**

# Special case: Minimizing the misclassification rate

$$\frac{P(s_1|\mathbf{x})}{P(s_0|\mathbf{x})} > \frac{\lambda_{10} - \lambda_{00}}{\lambda_{01} - \lambda_{11}} \quad \text{then } a_1 \text{ (decide class 1)}$$

Assume that the loss is only for error, and it's the same for both types of error:

$$\lambda_{10} = \lambda_{01} \quad \text{and} \quad \lambda_{00} = \lambda_{11} = 0$$

Then the decision rule simplifies to the following:

$$\begin{aligned} \frac{P(s_1|\mathbf{x})}{P(s_0|\mathbf{x})} > 1 \quad &\text{then } a_1 \text{ (decide class 1)} \\ &\text{else } a_0 \text{ (decide class 0)} \end{aligned} \quad \begin{array}{l} \text{Pick whichever class is more} \\ \text{likely given the data} \end{array}$$

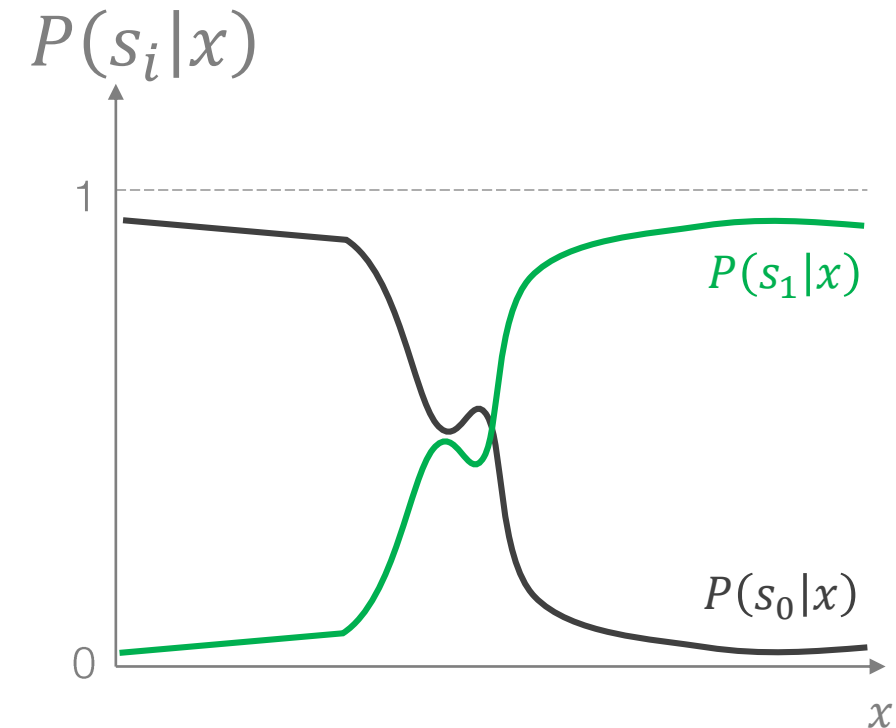

# Recall Bayes' Rule

Note: The **evidence** is just a normalizing constant to make sure the posterior integrates to 1

$$\overset{\text{Posterior}}{P(s_i|x)} = \frac{\overset{\text{Likelihood}}{P(x|s_i)} \overset{\text{Prior}}{P(s_i)}}{\overset{\text{Evidence}}{P(x)}}$$

## Posterior

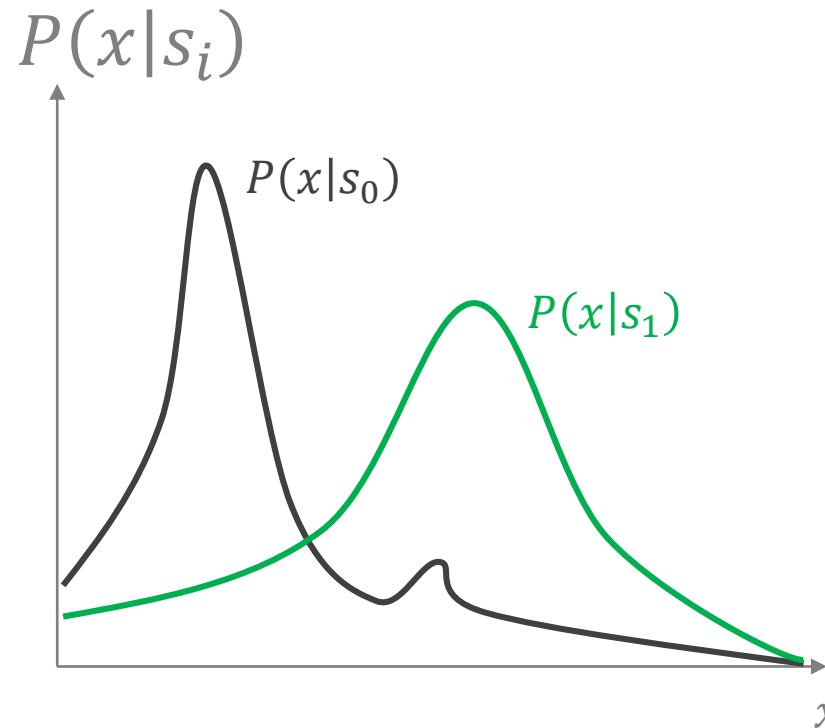

Answers the question: after seeing the data – which class is it most likely to belong to? Summing this across classes equals 1.

**Discriminative** models estimate this

## Likelihood

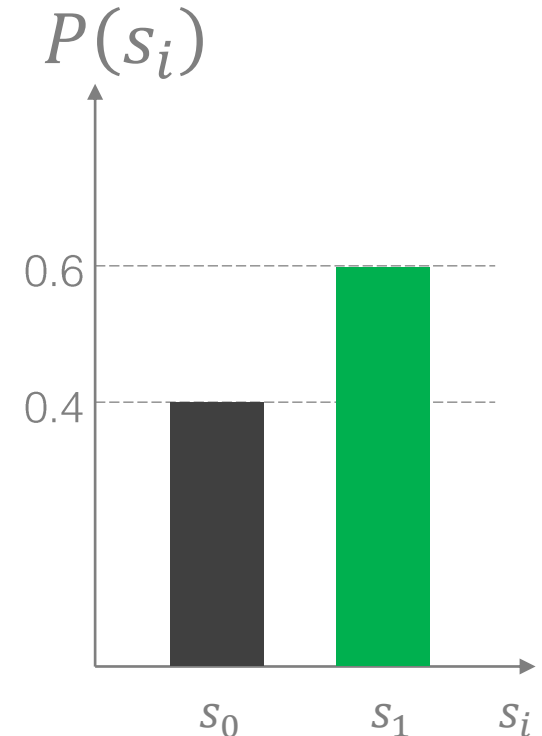

Answers the question: if I knew which class a sample belongs to, how are the data distributed?

**Generative** models estimate this

## Prior

Answers the question: what do I anticipate is the balance between my classes?

# Generative and discriminative models

Unobservable  
state of the world

Data Generating  
Process

$$p(X, Y)$$

**Types of models.** We can either model the full data generating process **OR** the target function, the mapping of  $x$  to  $y$

→ If we model this process, it's a **generative model**

- Models  $P(x|y)$
- Can be used to generate synthetic data and impute missing values
- Examples: naïve Bayes, linear discriminant analysis, hidden Markov models

**Target Function** for  
predicting  $y$  from  $x$

$$f(x) \rightarrow y$$

→ If we model this function, it's a **discriminative model**

- Model  $P(y|x)$  OR directly map  $x$  to  $y$  without probabilities
- Often better performance for large sample sizes
- Examples: logistic regression, support vector machines, neural networks, k nearest neighbors

# Takeaways

To make a decision:

1. Define a measure of risk or reward
2. Select the action that optimizes that metric

Decision theory informs how to operate supervised learning algorithms in practice

Decision theory incorporates relative importance of different error types

Generative models estimate  $P(x|y)$ , while discriminative models estimate  $P(y|x)$
